What is fracturing?

Fracturing is the process of creating fractures or cracks in the rock, so that oil or gas can flow through the fractures.
Explosive Fracturing

Explosive fracturing was used in Pennsylvania starting in the 1860s.

Nitroglycerin “torpedos” were lowered into wells and detonated.
Hydraulic fracturing was commercially developed in the late 1940s.

Water or some other fluid is pumped into a rock formation at sufficiently high pressure to fracture the rock.

Proppants (typically sand) and additives are also used.
Benefits of Fracturing

- Jobs, revenue to mineral owners, and revenue to local and state government
- Less dependence on imported oil and gas
- Natural gas is clean burning, can displace coal for use in generating electricity
Concerns about Fracturing

- Fear of groundwater contamination
### Distance Between Shale and Water

Fracturing Fluid Composition

- Louisiana enacted mandatory disclosure regulations effective October 20, 2011

- FracFocus
Concerns about Fracturing

- Fear of groundwater contamination
- Amount of water use
Amount of Water Used

- 3 to 5 million gallons per horizontal well
- not high compared to other industrial and agricultural uses
- 5 million gallons is about as much as is used to irrigate 8 to 10 acres of corn
- can be a problem when and where water already is in short supply
Concerns about Fracturing

- Fear of groundwater contamination
- Amount of water use
- Disposal of flowback
Disposal of Flowback

- In Texas and Louisiana, most disposal is by underground injection

- Not many underground injection wells exist in Pennsylvania
Disposal of Flowback

- EPA announces plans to develop Clean Water Act regulations to require pre-treatment of flowback prior to it being sent to treatment plants by 2014
Effects on Industry

- Increased production of oil and gas
- Gas prices low
- Significant pipeline additions
- Decreased imports of gas, possible exports of gas, decreased imports of crude
- New regulations, studies, controversy
